## DETERMINING WHETHER A NUMBER IS PRIME OR COMPOSITE

It is well known that an integer is a prime if its only divisors are one and N . It is a composite if it is also devisable by additional integers. Thus $\mathrm{N}=5720371$ is a prime while $N=368159$ is a composite. One of the easiest ways to distinguish between the two types of numbers is to carry out an evaluation of sigma( N )-1, where sigma( N ) is the summation point function of number theory. We want here to derive a few other ways to distinguish primes from composite numbers.

We start by looking at the ratio-

$$
\sigma\left(p^{\wedge} 3\right) / \sigma\left(p^{2}\right)=\left(1+p^{2}+p^{\wedge} 2+p^{\wedge} 3\right) /\left(1+p+p^{\wedge} 2\right)=1+p^{\wedge} 3 /\left(\sigma\left(p^{2}\right)\right.
$$

, where $p$ are primes. Multiplying this expression by $\sigma\left(\mathrm{p}^{\wedge} 2\right)$ produces the result-

$$
0=\sigma\left(p^{3}\right)-\sigma\left(p^{2}\right)-p^{\wedge} 3
$$

If one now replaces $p$ by any positive integer $n$, we get the related point function-

$$
\mathrm{H}=\sigma\left(n^{3}\right)-\sigma\left(n^{2}\right)-\mathrm{n}^{\wedge} 3
$$

It has zero value only if n is a prime but not otherwise. Hence we have a new criterion for a number being prime, namely that H vanishes. Here is a short table confirming when n is a prime-

| $n$ | $H$ | $N$ | $H$ |
| :--- | :--- | :--- | :--- |
| 1 | --- | 11 | 0 |
| 2 | 0 | 12 | 2949 |
| 3 | 0 | 13 | 0 |
| 4 | 32 | 14 | 2857 |
| 5 | 0 | 15 | 2462 |
| 6 | 293 | 16 | 3584 |
| 7 | 0 | 17 | 0 |
| 8 | 384 | 18 | 9716 |
| 9 | 243 | 19 | 0 |
| 10 | 1123 | 20 | 10851 |

The primes and the corresponding H are marked in red. Let us try the prime criterion for a couple of large numbers. First take-

$$
n=2^{\wedge} 32+1=4294967297
$$

Here we get in a split second that $\mathrm{H}=123805827909698676164362246$. So the number is composite. Next take -
n=6209613847

Here we get $\mathrm{H}=0$ so the number is a prime.
Another way to detect whether a number is prime or composite is to start with the numberfraction for powers of primes. This function is defined as-

$$
\mathrm{f}\left(\mathrm{p}^{\wedge} \mathrm{n}\right)=\left(\sigma\left(p^{n}\right)-p^{n}-1\right) / p^{\wedge} n
$$

Next take the ratio -

$$
f\left(p^{\wedge} 3\right) / f\left(p^{\wedge} 2\right)=(p+1) / p
$$

This can be rewritten as -

$$
1=1 / p f\left(p^{\wedge} 2\right)
$$

So that the right hand side for primes will be one. Relaxing the $\mathrm{n}=\mathrm{p}$ condition allows us to re-write things as-

$$
F=1 /\left(n f\left(n^{\wedge} 2\right)\right)
$$

, with $F=1$ occurring when $n=p$ and $F$ less than unity for composite numbers. Here $\mathrm{F}]=1$ meaning $\mathrm{p}=41$ is a prime.

Besides the simple existing criterion for primeness being sigma $\sigma(\mathrm{N})-1=\mathrm{N}$, we have found two other rules which may be applied to any positive integer to determine whether N is a prime or composite, They yield primes if-

$$
H=\operatorname{sigma}\left(n^{\wedge} 3\right)-\operatorname{sigma}\left(n^{\wedge} 2\right)-n^{\wedge} 3=0
$$

and/or

$$
\mathrm{F}=1 /\left[\mathrm{nf}\left(\mathrm{n}^{\wedge} 2\right)\right]=1
$$
